Audits and data security

The audit compares an ideal setup with what is currently possessed. We diagnose if the infrastructure and resources are secure, maintain data integrity, and deliver reliable information. We ensure:

1. Basic IT infrastructure audit

A basic audit will verify the current IT infrastructure and propose planning an optimal setup and expansion. We verify the status of the current infrastructure, programming (licences), and any systems integral to the operation of the business.

2. Analyzing IT infrastructure functionality

Analyzing if systems are outdated and comparing the current state with best practices accepted in companies of a similar size, location, and job sector.

3. Advanced IT security audit

An audit focused on your business' security; from physically securing your equipment to digital security.

4. Developing and verifying a Systems Security Plan

We prepare or verify the current Security System Plan. We detail security procedures for your infrastructure and procedures in case of an emergency.

5. Configuration audit: verification of services settings (internal and external)

Specialized audit focusing on specific IT systems: analyzing their configuration, optimizing them, and bringing them to industry standard.

6. Penetration tests for internet based services

Practical security tests combined with auditing. We deliver detailed documentation, propose improvements, and provide training where needed.
